AB The use of cardiac troponins in the diagnosis of acute myocardial
infarction has changed our understanding of coronary

artery disease. Cardiac troponins are slowly released from necrosing myocardium so they are detectable in blood for several days. This prolongs the opportunity for identifying an infarction. Cardiac troponins have therefore significantly reduced the diagnostic role of creatine kinase-MB isoenzyme. Although there is only one assay for cardiac troponin T, confusion can arise because there are different non-standardised laboratory assays for cardiac troponin I. However, the clinically important issue is the detection of troponin rather than its absolute concentration. Of other new markers high sensitivity C-reactive protein may have a role in potential risk stratification, but it is not currently recommended for routine clinical use. In the context of the future diagnosis of other cardiac conditions, the neuroendocrine hormone, B-type natriuretic peptide may have a role in the diagnosis and monitoring of cardiac failure.

AB In light of the increasing prevalence, morbidity, and mortality of heart failure, effective preventative strategies are urgently needed. Risk factors for heart failure include coronary artery disease and other atherosclerotic vascular diseases, hypertension, diabetes, renal insufficiency, obesity, and family history of cardiomyopathy. Essential strategies for prevention of heart failure are modification of risk factors for heart failure development; comprehensive hypertension, atherosclerosis, and diabetes treatment; and detection and treatment of asymptomatic left ventricular dysfunction. The B-type natriuretic peptide assay may aid in identifying asymptomatic left ventricular dysfunction in patients with risk factors for heart failure. In patients with hypertension, atherosclerosis, and/or diabetes, angiotensin-converting enzyme inhibitor, β -blocker, aspirin, and statin therapy can prevent progression to symptomatic heart failure. Avoidance of calcium channel-blockers as first-line antihypertensive therapy can also reduce the risk of heart failure. There remain substantial opportunities to improve implementation of therapies proven to prevent heart failure in the large number of patients at risk. .COPYRGT. 2003 MedReviews, LLC.

AB A noninvasive biochemical testing method for early detection and monitoring the condition of cardiac complications in hemodialysis (HD) patients would be useful and might lead to improved survival. The aim of this study is to clarify the pathophysiological significance of plasma brain natriuretic peptide (BNP) levels in HD patients with and without coronary artery disease (CAD). We measured plasma atrial natriuretic peptide (ANP) and BNP levels on Monday, Wednesday, and Friday before and after HD in 28 consecutive patients who underwent HD three times weekly. In addition, we measured plasma ANP and BNP levels in 21 HD patients with CAD and 27 HD patients without CAD and studied the relationships between BNP levels and cardiac function and clinical variables. Plasma ANP levels significantly decreased after HD on Monday, Wednesday, and Friday, and predialysis plasma ANP levels on Monday were significantly greater than those on other days. Plasma BNP levels did not change after HD on Monday; however, they significantly decreased after HD on Wednesday and FRIDAY: Predialysis plasma BNP levels on Monday were greater than those on other days, and postdialysis plasma BNP levels on Monday were greater than predialysis plasma BNP levels on WEDNESDAY: Plasma BNP levels in HD patients with CAD were significantly

greater than those in HD patients without CAD and significantly correlated with left ventricular (LV) ejection fraction ($r = -0.69$), end-diastolic volume index ($r = 0.59$), and end-systolic volume index ($r = 0.84$) determined by left ventriculography. Conversely, plasma BNP levels in HD patients without CAD significantly correlated with LV mass index ($r = 0.54$) determined by echocardiography and mean systolic blood pressure ($r = 0.72$) determined by 48-hour ambulatory blood pressure monitoring. These results suggest the following: (1) plasma BNP levels before and after HD in chronic HD patients directly correlate with the degree of body fluid retention, and the day of the week on which the sample is obtained should be considered for its evaluation; (2) plasma BNP levels reflect LV function in HD patients with CAD; and (3) plasma BNP levels reflect LV mass and blood pressure in HD patients without CAD.

AB BACKGROUND: Myocyte death could play a role in heart failure (HF) irrespective of the presence of **coronary artery disease**. The study aimed to assess this hypothesis by use of the cardiac troponin I (cTnI) assay. METHODS AND RESULTS: Seventy-one patients with nonischemic HF, New York Heart Association (NYHA) class II-IV, with a normal coronary angiogram and after exclusion of myocardiopathies were evaluated in the study. The control group included 9 healthy subjects and 15 patients hospitalized for severe noncardiac dyspnea. Cardiac TnI concentrations were determined at admission with a research reagent (cTnIus) characterized by a detection limit of 0.026 ng/mL and a high analytic sensitivity of 0.002 ng/mL. cTnIus levels were more than 0.026 ng/mL in 19 HF patients, ranging between 0.027 and 0.463 ng/mL, whereas no cTnIus level was detectable in the control group. With use of a reference assay, only 2 HF patients had abnormal cTnI values. Severe HF was observed in 17 of these 19 patients, assessed by NYHA class IV or by the presence of pulmonary edema. Patients with an increased cTnIus level had a more restrictive mitral Doppler pattern ($P < .001$) and a more distinctive left ventricular (LV) concentric remodeling ($P < .0001$), whereas LV ejection fraction was similar in both HF groups. The increased cTnIus level was also associated with a LV wall strain biologic marker (ie, an increased brain natriuretic peptide plasma level) ($P < .001$). CONCLUSIONS: cTnI assay is a promising biochemical method for detecting cardiac myolysis in HF, independent of the presence of **coronary artery disease**. This subtle myolysis could be in part related to the severely increased LV wall strain.

AB Interleukin-6 (IL-6), a proinflammatory cytokine, plays a key role in the pathogenesis of coronary artery disease (CAD). We investigated circulating IL-6 and its receptors in patients with CAD. We evaluated 39 Japanese patients with CAD (30 males and 9 females aged 36-79 years), measuring their plasma levels of IL-6 and IL-6 receptors alpha and beta (IL-6Ralpha, IL-6Rbeta). Circulating levels of IL-6, IL-6Ralpha and IL-6Rbeta were measured by an enzyme-linked immunosorbent assay. Blood was sampled immediately after admission and again after 1, 2, 3, 6 and 9 h, then every 12 h for 5 days. Atrial natriuretic peptide (ANP) and B-type natriuretic peptide (BNP) were measured on day 3 after symptom onset. Plasma levels of IL-6 and IL-6Rs were significantly increased in 28 patients with acute myocardial infarction (AMI) compared with 15 normal controls. However, neither IL-6 nor IL-6Rs showed an increase in 6 patients with angina pectoris. We observed two peaks for circulating IL-6 in AMI, the first of which showed a significant correlation with ANP as well as BNP. These results may help to explain why the amount of IL-6 produced is closely related to the severity of myocardial dysfunction in patients with CAD.
